

## **SMART TEST ATTRIBUTES**

### **Background of the Invention**

5                   Test automation systems are used to automatically test software-driven systems. Conventional architectures consist of a test harness, which is typically used to execute test cases specified by attributes of the test cases. The attributes are used to label classes or methods to mark which of the classes or methods should be examined for testing.

10                   A conventional test harness examines each of the classes and/or methods, examines the attributes present, and then based on the examination of the attributes performs an action. This method of using attributes requires that the code necessary to perform an action be present in the test harness. Accordingly, it is not possible to create new kinds of test attributes without modifying the test harness.

15                   Additionally, the same code often needs to be written (or modified) for each different test harness in which the attribute is used. Likewise, adding new attributes can lead to undesirable changes in existing tests in a conventional test harness. The variety of functionality in conventional test harnesses can result in differences between the test harnesses such that a test may return different results in different test harnesses (this

20                   may also result in tests that only run properly in one test harness), which is undesirable.

                  In accordance with the present invention, attributes can be reused and new attributes added without requiring modifications to test harnesses in order run tests.

### **Summary of the Invention**

                  The present invention is directed towards smart test attributes, which are

25                   objects that are arranged to incorporate test functionality in the attributes themselves and to provide a standard way to interact with the attributes through a set of interfaces. The set of interfaces includes interfaces for class level attributes, method level attributes, and parameter level attributes. Test class attributes can be used to modify an instantiated object state, skip test extraction from a class, or cause test extraction to be

performed multiple times for a denoted type. Method level attributes are capable of modifying method parameters and method execution. In an embodiment, method level attributes include execution attributes and supplemental attributes. Parameter level attributes are optionally used to modify the parameter input to a method and/or to  
5 modify a state of an object (e.g., the context) after a method has executed.

According to one aspect of the invention, a computer-readable medium having computer-executable components comprises three components. A test case scenario object comprises test methods that are arranged to test an electronic system. A test harness is arranged to provide system test services for the test methods. Smart  
10 attributes are arranged in a hierarchy that comprises method level attributes that are arranged to modify parameters of a test method and modify execution of the test method, and parameter level attributes that are arranged to modify the parameter input to the test method and to modify a state of an object after the test method has executed.

15 According to another aspect of the invention, a method for automated testing comprises providing smart attributes that comprise method level attributes and parameter level attributes. Test methods are provided that are arranged to test an electronic system, wherein the test methods are stored in a test case scenario object. System test services are provided for the test methods. Method level attributes are used  
20 to modify parameters of a test method and modify execution of the test method. Parameter level attributes are used to modify the parameter input to the test method and to modify a state of an object after the test method has executed.

According to yet another aspect of the invention, a system for automated testing comprises three components. A test case scenario object comprises test methods  
25 that are arranged to test an electronic system. A test harness is arranged to provide system test services for the test methods. Smart attributes are arranged in a hierarchy that comprises method level attributes that are arranged to modify parameters of a test method and modify execution of the test method, and parameter level attributes that are arranged to modify the parameter input to the test method and to modify a state of an  
30 object after the test method has executed.

According to a further aspect of the invention, a system for automated testing comprises five means. Means for providing smart attributes that comprise method level attributes and parameter level attributes. Means for providing test methods that are arranged to test an electronic system, wherein the test methods are stored in a test case scenario object. Means for providing system test services for the test methods. Means for using the method level attributes to modify parameters of a test method and modify execution of the test method. Means for using the parameter level attributes to modify the parameter input to the test method and to modify a state of an object after the test method has executed.

10

### **Detailed Description of the Preferred Embodiment**

Throughout the specification and claims, the following terms take the meanings explicitly associated herein, unless the context clearly dictates otherwise. The terminology and interface specifications used herein are not intended to represent a particular language in which a particular object or method should be written. Rather, the terminology and interface specifications are used to describe the functionality and contents of an interface or object, such as function names, inputs, outputs, return values, and what operations are to be performed using the interface (or what operations are to be performed by the object).

### Illustrative Operating Environment

With reference to FIGURE 1, one exemplary system for implementing the invention includes a computing device, such as computing device 100. In a very basic configuration, computing device 100 typically includes at least one processing unit 102 and system memory 104. Depending on the exact configuration and type of computing device, system memory 104 may be volatile (such as RAM), non-volatile (such as ROM, flash memory, etc.) or some combination of the two. System memory 104 typically includes an operating system 105, one or more applications 106, and may include program data 107. In one embodiment, application 106 may include a word-processor application 120 that further includes ML editor 122. This basic configuration is illustrated in FIGURE 1 by those components within dashed line 108.

Computing device 100 may have additional features or functionality. For example, computing device 100 may also include additional data storage devices (removable and/or non-removable) such as, for example, magnetic disks, optical disks, or tape. Such additional storage is illustrated in FIGURE 1 by removable storage 109 and non-removable storage 110. Computer storage media may include volatile and nonvolatile, removable and non-removable media implemented in any method or technology for storage of information, such as computer readable instructions, data structures, program modules, or other data. System memory 104, removable storage 109 and non-removable storage 110 are all examples of computer storage media. Computer storage media includes, but is not limited to, RAM, ROM, EEPROM, flash memory or other memory technology, CD-ROM, digital versatile disks (DVD) or other optical storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to store the desired information and which can be accessed by computing device 100. Any such computer storage media may be part of device 100. Computing device 100 may also have input device(s) 112 such as keyboard, mouse, pen, voice input device, touch input device, etc. Output device(s) 114 such as a display, speakers, printer, etc. may also be included. These devices are well known in the art and need not be discussed at length here.

Computing device 100 may also contain communication connections 116 that allow the device to communicate with other computing devices 118, such as over a network. Communication connection 116 is one example of communication media. Communication media may typically be embodied by computer readable instructions, data structures, program modules, or other data in a modulated data signal, such as a carrier wave or other transport mechanism, and includes any information delivery media. The term “modulated data signal” means a signal that has one or more of its characteristics set or changed in such a manner as to encode information in the signal. By way of example, and not limitation, communication media includes wired media such as a wired network or direct-wired connection, and wireless media such as acoustic, RF, infrared and other wireless media. The term computer readable media as used herein includes both storage media and communication media.

The present invention is directed towards smart test attributes, which are objects that are arranged to incorporate test functionality in the attributes themselves and to provide a standard way to interact with the attributes through a set of interfaces. The set of interfaces includes interfaces for class level attributes, method level attributes, and parameter level attributes. Test class attributes can be used to modify an instantiated object state, skip test extraction from a class, or cause test extraction to be performed multiple times for a denoted type. Method level attributes are capable of modifying method parameters and method execution. In an embodiment, method level attributes include execution attributes and supplemental attributes. Parameter level attributes are optionally used to modify the parameter input to a method and/or to modify a state of an object (e.g., the context) after a method has executed.

## Test Automation System Architecture

FIGURE 2 is a block diagram illustrating an exemplary environment for practicing the present invention. The exemplary environment shown in FIGURE 2 is a test automation system 200 that comprises test harness 210, test runtime 220, and test case scenario 230.

## Test Runtime

In one embodiment, test runtime 220 is a collection of objects that abstracts knowledge of test cases from the test harness. Test runtime 220 typically comprises test services provider object 221, extraction engine 222, attributes 223, and test method executor 224. Test runtime 220 can be used by different harnesses to provide consistent support for a particular type of test case format. By extension, a test harness can use different test runtimes to support different types of test case formats. The test harness typically determines which test runtime to use for a particular test case format.

Test case extraction is accomplished through a dedicated extraction object (obtained from a test services provider object 221, described below), and invocation is performed by an object (test method executor 224, also described below), which returns a generic result to the test harness. The test method executor evaluates attributes using a generic interface to control the execution of the method.

A test harness is not required to, for example, evaluate attributes, determine the order that in which test methods should be executed, build argument lists for method invocations, and the like. The test harness typically does not have direct access to this information required to perform those tasks, which helps ensure more consistent test execution between different test harnesses. All test harness dependent functionality (logging, “remoting,” and the like) should be objects implemented by the test harness, described by an interface, and stored in the test service provider object for use during test execution. Accordingly, a test harness can be created which is easily capable of switching between different test runtimes without requiring changes to the test harness code.

## Test Services

Test services provider object 221 is used by the test harness to retrieve an extraction engine and is also used by the test case scenario to retrieve objects for test harness-implemented functionality (including test services such as logging, synchronization, and the like).

The test services provider object typically provides methods that are used to facilitate access to test services. An AddService method is called to store references to objects that implement a test service. A test service object should implement a “generic” type, which facilitates a set of standard services that different harnesses can provide. The object passed in should implement functionality needed by attributes or test methods. This method should be called by the test harness for each service the test harness provides, which is generally done before the test methods are executed.

A GetService method is typically called to retrieve a type of test service object. The type passed in should represent an interface implemented by a test service object. An object that implements that object will be returned if found. If the object is not found, a value is returned that indicates such a result (e.g., returns a null). If a test or attribute requires a test service that is not present, the test method being executed should fail.

An AddDefaultServices protected method is typically called by the constructor. It is typically used to add whatever test services the test runtime provides by default, such as an extraction engine.

The test services provider object data and method calls should be static such that the data set by the test harness can be retrievable by other calls to the test service provider at a point later in time. The object is typically a class that implements the functionality described above. The constructor of the object is typically used to call the AddDefaultServices method.

### Extraction Engine

Extraction engine 222 is used to retrieve an ordered list of test methods from the test case for the test harness for a particular test case scenario. Typically there is only one extraction engine present in a test runtime.

A GetTestMethodWrappers method is used to retrieve the ordered list of test methods for a test case scenario. (A test method wrapper is a particular implementation of a test method executor.) A parameter is passed into the method that represents a container that holds test cases. The method returns the ordered list of

methods. If an error occurs while extracting the test case, an exception can be “thrown.” If no test cases or test methods are found, an empty list is normally returned. An empty list is usually treated as a failure by the test harness. If additional data needs to be passed to the extraction engine, it can be provided through the

- 5 TestServiceProvider object by a TestHarnessDataProvider test service.

A large part of the functionality present in an extraction engine object is the same between different runtimes; the only detail that may change significantly from one runtime to another is which attributes are used. An object should be created in order to facilitate easy creation of new extraction engines and runtimes. This class  
10 typically implement the functions:

TypeIsATestCase returns a “true” if the type passed in is a test case, “false” if not. This function examines the attributes present on a type by looking for a test case attribute to determine if a type is a test case or not.

- MethodIsATestMethod returns true if the method passed in is a test  
15 method, false if not. This function examines the attributes present on a type by looking for an execution attribute to determine if a type is a test method or not.

- GetMethodWrappersFromType gathers all relevant public non-static methods on a type that have execution attributes and returns the methods as an ordered list of MethodWrappers (discussed below). In an embodiment using the .Net  
20 environment,, the list is ordered using the sort functionality built into .Net arrays so that the MethodWrapper calls a compare routine to order the list. If an instance of the type cannot be created, this method fails and returns an empty list.

- The extraction engine can use a test service to retrieve information that can be used to modify a test extraction. The information can be stored in a file such as  
25 an XML file that is in accordance with a schema defined for storing test extraction information. If the data provided by the test service does not refer to an XML file in accordance with the schema, the modification data can be ignored.

- The extraction engine typically loads all extraction modifier XML files specified. The contents of the XML files are, for example, placed into two “buckets:”  
30 test inclusions, and test exclusions. If both buckets are empty, the extraction engine

should include all tests. This case is equivalent to having no extraction modifier xml files, or not being able to retrieve the Extraction Engine Data Source test service. If only the exclusion bucket is empty, the extraction engine should include all tests. If only the inclusion bucket is empty, the extraction engine should include all tests, and  
5 exclude tests listed in the exclusion bucket. If both buckets have data, the extraction engine should include tests in the inclusion bucket that are not listed in the exclusion bucket (such that the exclusion list has controlling authority over the inclusion list).

### Test Method Executors

10                   Test method executors 224 are used to execute a test method without requiring the caller to have beforehand knowledge about the method or its attributes. An Invoke method is called to execute a test method. An object holding the result of the operation is returned (pass, fail, skip, and the like). The Invoke method is responsible for processing the attributes associated with a method and creating a  
15 parameter list (if required) for the method being invoked. Execution is typically modified by the attributes associated with the test method.

                  An Abort method can be called to abort a currently executing test method. The abort typically causes a currently running Invoke method to return. After an abort is performed, no further tests can normally be run.

20                   A CompareTo method is called to compare two Test Method Wrappers. If the result returned is less than zero, it indicates that this method should be executed before the other Test Method Wrapper (to which the method is compared). If the result returned equals zero it indicates that the order in which both methods are executed in does not matter. If the result returned is greater than zero, it indicates that this method  
25 should be executed after the other Test Method Wrapper.

                  A GetMethodAttributes method is called to retrieve sorted list of attributes associated with the test method, which are derived from a common base method attribute class. This sorted list of attributes is used by the Test Method Wrapper in several locations. For example, the Invoke method (as discussed above) uses the  
30 sorted list to evaluate the attributes in the correct order. Also, the GetMethodAttributes

can be used to compare one method wrapper to another. A call such as “get AttributesDescription” uses the ordered list of attributes to create a string description of the attributes associated with the method.

5       The test method wrapper has several properties that can be retrieved for use by the test harness, such as by calling “get Description” and “get Name.” The properties are generated from the name of the method and the class from which the method was defined. Other properties can be added as needed. Note that these properties do not require the harness to know anything about the test method being queried and that additional properties can be added without requiring modifications to  
10       existing test harnesses.

      The MethodResult object is used to convey the result of a test method wrapper to the test harness. Because the test harness does not necessarily have beforehand knowledge of the method being invoked, the results are expressed in abstract form.

15       The object typically needs to express three possible outcomes from trying to execute a method: pass, skip, or fail. A “pass” would typically indicate that the method completed execution without any errors (for example, the method logged no failures, the test method did not throw an exception, and none of the attributes had an error). An “error” would indicate that the method failed (for example, the test method  
20       indicated a failure, or an attribute indicated a failure). A “skip” would indicate that the method was skipped rather than executed (for example, an attribute specifies the test method should only run on a server, but the test is running on a client machine; in which case the method would be skipped).

      The MethodResult object can also contain optional messages such as a  
25       result message and/or an error message. The result message can be a human readable description of the methods result. Upon a successful execution of a method, this could be left blank, or it could contain the number of passes recorded. For a completed method in which an error occurred, a textual description of the error may be included while the error message can contain the details of the error.

When an exception is “thrown” by an attribute a `TestConditionException` class can be used to convey a modified method state. For example, three derived classes that map directly to a method state include `TestSkipException`, `TestSucceededException`, and `TestErrorException`.

5                   Attributes 223 are typically used to modify and control the execution of a test. A test is executed according to a test case scenario, which can be defined through the use of attributes. At least three basic types of attributes can be used: class level attributes, method level attributes, and parameter level attributes.

10                   Test class attributes are optional and can be used to modify an instantiated object state, such that test extraction can be skipped or caused to be performed multiple times for a denoted type. Pre- and post-extraction methods are typically used to modify the instantiated object state. Test class attributes allow such variations in test case scenarios to be implemented.

15                   Method level attributes are capable of modifying method parameters and method execution. In an embodiment, method level attributes include execution attributes and supplemental attributes. Both attributes have pre- and post-invocation methods. The order in which method level attributes are evaluated is determined by an order property, which is defined when the attribute is written; however, attributes typically have no beforehand knowledge of what other attributes may be present.

20                   Execution modification at each stage can be handled by a priority based state system – the attribute returning a state with the highest priority is typically used to determine how execution is modified.

25                   Execution attributes are used to mark a method as a test method. A method without an execution attribute is usually not included in a test. The core responsibility of an execution attribute is to establish a high-level order to the test and to evaluate method results. A method should not have more than one execution attribute. Extraction and execution behavior when more than one execution attribute is present is normally undefined. Examples of execution attributes include “Setup”, “Step”, and “Teardown” attributes.

Supplemental attributes perform supplemental actions to modify the execution of a test method. The core responsibility of a supplemental attribute is to perform secondary tasks that are necessary for the execution of a test. They typically are not used to denote high-level order. A method may have any number of  
5 supplemental attributes. Examples of supplemental attributes include “WaitFor” and “Target” attributes.

Parameter level attributes are optionally used to modify the parameter input to a method and to modify a state of an object (e.g., the context state) after a method has executed. A parameter level attribute is normally not used to alter the  
10 execution of a test as method level attributes are used. However, if an exception is thrown, the test method fails immediately in response to the exception. In an embodiment, there is only one parameter level attribute per parameter; behavior with more than one parameter level attribute is left undefined. Parameter level attributes are evaluated after method level attributes are evaluated before a method is invoked, and  
15 before method level attributes are evaluated after a method is invoked. An example of a parameter level attribute includes the “ContextMapping” attribute.

The MethodState object is used by method attributes to control the execution of a test method. Because a plurality of attributes can be assigned to a test method (and because each attribute can potentially alter the execution of the test  
20 method), each attribute can communicate with the MethodState object to ensure consistent execution of the test method.

The MethodState object can comprise information related to the execution state, a message, an error code, and a state override priority. The execution state comprises information regarding how the method has terminated (e.g., skip, pass, fail), whether the state is permitted to be changed, and whether the method should be  
25 executed. The message can be used to optionally present text that indicates why the test method is in a particular state. The error code can be used to indicate the details of an error that the test method wrapper might encounter while executing a test method. The state override priority field can be used to improve the consistency of test method

execution by allowing the execution state, message, and the error code to be altered only if the new state has a priority greater than the existing state.

The test method wrapper (224) executes a test method until a terminating state is reached. When the terminating state is reached, the MethodResult object is  
5 constructed from the final MethodState object.

Execution attributes are responsible for parsing the result obtained from a method invocation. To determine if a method passed or failed, logs can be monitored for pass and fail entries. If any failures are logged, the method likely failed. If no  
10 passes or failures were logged, the method also likely failed. If an exception was thrown from the test method or any attributes, the method again likely failed. Otherwise the method can be considered to have (successfully) passed.

### Test Case Scenario

In one embodiment, test case scenario 230 is a collection of objects that  
15 coordinate the execution of test methods for a particular test case. The test methods can be written without beforehand knowledge of the test harness because of the interface provided by and through the test method executor (224).

Test case scenario 230 typically comprises test methods 231 and other methods and data 232. Test methods access test harness objects by using the runtime  
20 object (which comprises the test method executor), rather than by querying specific test harnesses.

### Test Harness

In one embodiment, test harness 210 is a collection of objects that  
25 coordinate the execution of test cases and provides various test services. Test harness 210 typically comprises a UI (User Interface) 211, an Execution Engine 212, a Context object 213, and a Logging object 214. The test harness for purposes of added functionality may comprise other objects such as an automation system interface.

The execution engine (212) is responsible for loading and executing test  
30 case scenarios using the test runtime (220). FIGURE 3 illustrates of a process 300 flow

of an execution engine, in accordance with aspects of the invention. After a start block, the process moves to block 310, at which point a test runtime is loaded. In an embodiment wherein the test runtime is written in .Net, the test runtime assembly and test case scenario assembly is loaded into an AppDomain. The test harness can display  
5 information such as the version of the .Net runtime loaded, or the version of the test runtime being used.

At block 320, one or more test cases are loaded/compiled into memory. The test cases can be precompiled and loaded into memory or loaded into memory and then compiled. The test harness can display information about the test case scenario as  
10 well as whether the test case scenario loaded and/or compiled successfully.

Continuing at block 330, the extraction engine is obtained. The extraction engine is obtained by first retrieving the test services provider object (221). Next, the type of the base extraction engine is determined from the test method executor (220). The static GetService function on the test services provider object is called  
15 (passing the type of the base extraction engine to the test services provider object) to receive a reference to an extraction engine.

At block 340, test harness functionality is added to the test services provider. The AddService method on the test services provider is used to add to the test services provider the test services that are implemented on the test harness. The test  
20 services include objects that implement various interfaces such as the reboot mechanism, logging, context, and the like. If it is desirable to pass data to the extraction engine (such as, for example, an XML file to specify that certain method should be included or skipped), a test service object that implements a test harness data provider interface can be used.

At block 350, the extraction engine is used to get test case steps. The  
25 extraction engine obtained at block 330 is used to call a GetTestMethodWrappers method of the extraction engine, passing to the method the AppDomain holding the test case. An array of TestMethodWrappers is typically returned.

The array of method wrappers typically contains a list of test actions that should be executed in the order in which they are present in the array. (The extraction engine is typically responsible for ordering the array).

At block 360, the list of methods retrieved at block 350 is executed in the  
5 order in which the methods are listed. Each method is executed by calling the Invoke method. The invoke method typically returns details about the result the test action. The details may include a success/fail/skip result, as well as additional details. The details of the result may be, for example, logged, or used to update the UI.

FIGURE 4 illustrates of a process 400 flow of an execution engine, in  
10 accordance with aspects of the invention. For each test action, process 400 is repeated. The execution engine calls the InvokeInstanceMethod to initiate the execution of a particular test action. The InvokeInstanceMethod calls the InstanceMethod to invoke the particular test action. The InstanceMethod in turn calls the Method Wrapper (i.e., an example test method executor) to invoke the particular test action.

15 The method wrapper evaluates and executes the attributes (pre-invocation) of the particular test action. The method wrapper next invokes the test method in accordance with the evaluated/executed test method. After the test method has been executed, the attributes are again evaluated/executed (post-invocation). The method wrapper construes the result of the post-invocation attribute evaluation and  
20 returns a value that that signals the result. The ActionResult is passed to the InstanceMethod, and to the InvokeInstanceMethod in turn. The InvokeInstanceMethod evaluates the return value and passes the result to the execution engine.

25 As a further illustration of the invention, a listing of pseudocode is provided as follows:

ExtractionEngine.GetTestMethodWrappers

TestMethodWrappers [] methodWrappers;  
30 For ( each assembly in AppDomain )

```

{
    For ( each type in assembly )
    {
        If ( TypeIsATestCase(type) )
5         {
            methodWrappers +=
GetMethodWrappersFromType(type)
        }
    }
10 }

Return methodWrappers

ExtractionEngine.GetMethodWrappersFromType

TestMethodWrappers [] allMethodWrappers
15
ExtractionState curState = invalid state
Do
{
    TestMethodWrappers [] instanceMethodWrappers
20    curState.Reset()

    if ( type is creatable )
        Object testObject = new type;
    Else
25    Return empty list;

    For ( each attribute on type )
    {
        If ( attribute is kind of test case attribute )
30        curState = Attribute.PreExtract(testObject)
    }

    If ( curState = terminating state )
        break;
35

    MethodInfo [] potentialTestMethods =
type.GetAllPublicMethods()
    For ( each method in potentialTestMethods )
    {
40        If ( MethodIsATestMethod(method) )
        {
            TestMethodWrapper wrapper = new
Wrapper(obj, method)

```

```

        If (
!wrapper.GetMethodAttributes[0].Inherit )
        {
            If ( method.definingType == type )
5                instanceMethodWrappers += wrapper
        }
        Else
            instanceMethodWrappers += wrapper
    }
10 }

    For ( each attribute on type )
    {
        If ( attribute is kind of test case attribute )
15        curState = Attribute.PostExtract()
    }

    instanceMethodWrappers.Sort()
    allMethodWrappers += instanceMethodWrappers
20 }
While ( curState != terminating state ) // invalid state
or skip

Return allMethodWrappers;

25 TestMethodWrapper.Invoke

MethodState curState = invalid state
Do
{
    curState.Reset()
30

    TestMethodAttribute [] methodAttributes =
GetMethodAttributes()
    methodAttributes.Reverse()

35    // pre-invoke for all attributes
    Try
    {
        // method level attributes
        For ( each attribute in methodAttributes )
40        {
            MethodState newState =
attribute.PreInvoke(...)
            if ( newState.execstate != nochange &&

```

```

        newState.priority > curState.priority
    )
    {
        curState = newState
5    }
    }
    Catch(UnexpectedCondition)
    {
10        curState = new MethodState(UnexpectedCondition);
    }
    Catch(e)
    {
        // if an attribute throws an exception, the
15    invoke fails
        curState = new MethodState(e);
        break;
    }

20    // evaluate state and stop invoke if necessary --
    state must
    // be evaluated before examining parameter level
    attributes
    if ( curState.execstate == terminating state )
25    {
        break;
    }

    Try
30    {
        // parameter level attributes -- these
        attributes can't
        // modify state, but if they throw the invoke
        fails
